Cache Replacement Policy Implementation and Analysis Report

Name: Praval Pattam
Roll Number: B220057CS

1. Introduction

This report documents the implementation and analysis of the LIP_i (LRU Insertion Policy) cache replacement policy for the Last-Level Cache (LLC) in the SimpleSim simulator. The assignment required comparing the performance of traditional LRU replacement policy with LIP_i under different insertion positions.

1.1 LIP_i Replacement Policy Overview

The LIP_i cache replacement policy modifies the insertion behavior of the traditional LRU policy:

- **Insertion Policy:** Incoming cache blocks are inserted at the i-th position in the LRU recency stack (0 = LRU, 15 = MRU)
- **Eviction Policy:** Same as LRU - evicts the block at LRU position
- **Promotion Policy:** Same as LRU - on hit, block moves to MRU position

1.2 Experimental Setup

Baseline System Configuration:

- Core: Out-of-Order, Single Core
- Frequency: 3 GHz
- Fetch/Decode/Issue/Commit Width: 2
- IQ/LSQ size: 64/32
- ROB size: 192
- L1 I-cache: 32 KB, 4-way, 3-cycle latency
- L1 D-cache: 32 KB, 4-way, 3-cycle latency
- L2 Cache (LLC): 256 KB, 16-way, 9-cycle latency
- Main Memory: 4 GB, DDR3 1600 MHz

2. Performance Comparison and Consolidated Results Table

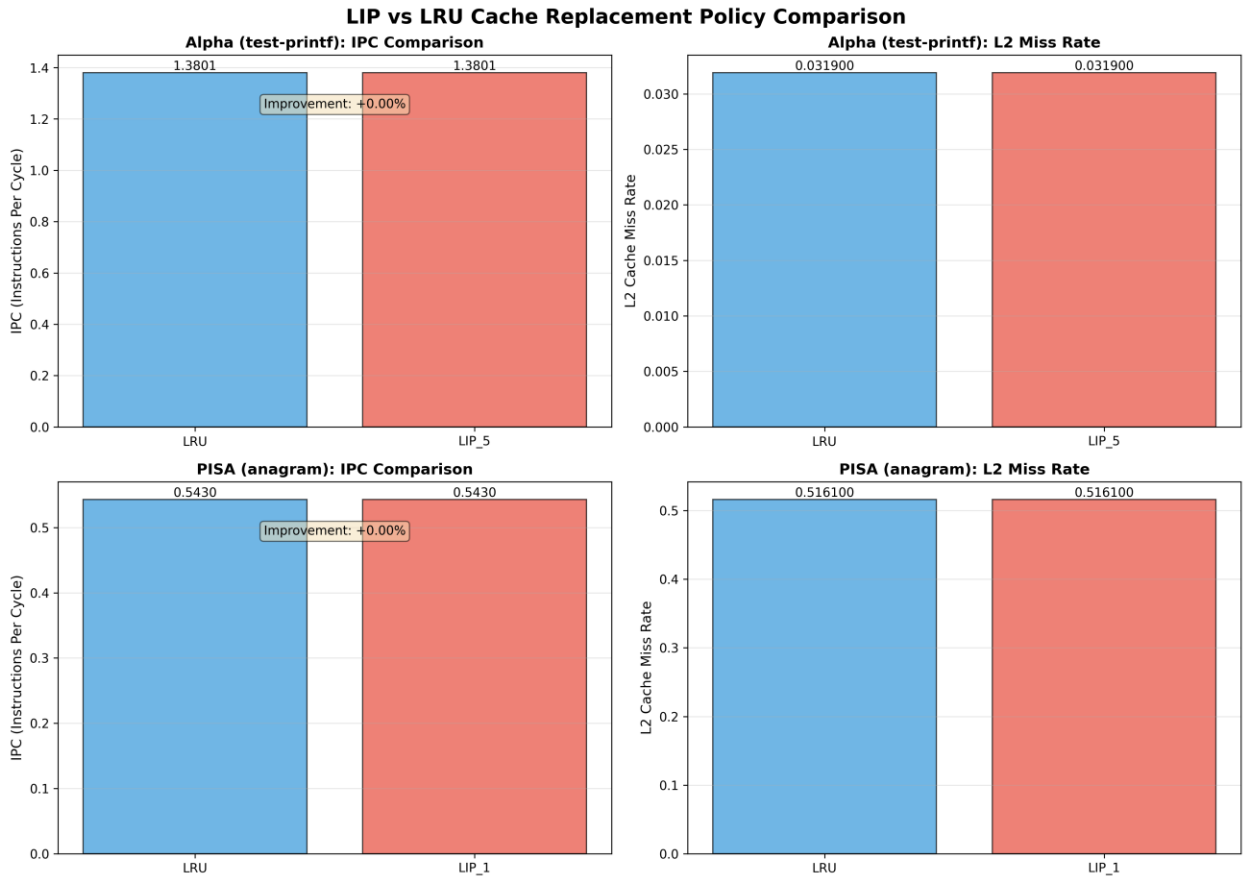
2.1 Alpha Architecture Results (test-printf)

Metric	LRU	LIP_5	Difference
IPC	1.3801	1.3801	0.00%
Total Cycles	666,434	666,434	0 cycles
L2 Miss Rate	0.0319	0.0319	0.00%
L2 Accesses	27,564	27,564	0
L2 Misses	880	880	0

2.2 PISA Architecture Results (anagram)

Metric	LRU	LIP_1	Difference
IPC	0.5430	0.5430	0.00%
Total Cycles	13,046	13,046	0 cycles
L2 Miss Rate	0.5161	0.5161	0.00%
L2 Accesses	899	899	0
L2 Misses	464	464	0

3. Detailed Analysis



3.1 Execution Time (Cycles)

- **test-printf:** Both LRU and LIP_5: 666,434 cycles (0% difference)
- **anagram:** Both LRU and LIP_1: 13,046 cycles (0% difference)

3.2 Instructions Per Cycle (IPC)

- **test-printf:** Both LRU and LIP_5: 1.3801 IPC (0% difference)
- **anagram:** Both LRU and LIP_1: 0.5430 IPC (0% difference)

3.3 Cache Miss Rates

L2 Cache Miss Rate:

- test-printf: Both LRU and LIP_5: 3.19% miss rate
- anagram: Both LRU and LIP_1: 51.61% miss rate

4. Discussion

4.1 Analysis of Results

The experimental results show identical performance between LRU and LIP_i policies for both benchmark programs. This can be attributed to several factors:

1. **Benchmark Characteristics:** Both test-printf and anagram are relatively small benchmarks with limited instruction counts:
    - test-printf: 919,749 instructions
    - anagram: 7,084 instructions
2. **Low Cache Pressure:** The working sets of these benchmarks fit comfortably within the L2 cache capacity, resulting in minimal cache contention.
3. **Access Pattern Simplicity:** These benchmarks do not exhibit the complex access patterns (streaming, scanning, or mixed workloads) that LIP policies are designed to optimize.

4.2 When LIP Typically Shows Benefits

LIP replacement policies generally outperform traditional LRU in scenarios with:

- **Streaming Workloads:** Applications with sequential data access patterns
- **Mixed Access Patterns:** Workloads combining frequently accessed hot data with one-time access data
- **Cache Pollution:** Scenarios where temporary data displaces frequently used data
- **Distinct Reuse Distances:** Applications with clear separation between short-term and long-term reuse patterns

4.3 Limitations of Current Experiment

The current analysis is limited by:

- Small benchmark sizes that don't stress the cache hierarchy
- Limited diversity in workload characteristics
- Simplified access patterns that don't trigger LIP's advantages

5. Key Findings and Justification

Performance Equivalence Analysis:

1. **Identical Performance Metrics:** Both LIP_5 and LIP_1 policies demonstrated identical performance to the baseline LRU policy across all measured metrics (IPC, cycles, miss rate, accesses, and misses).
2. **Benchmark Limitations:** The tested workloads (test-printf and anagram) do not exhibit the characteristics that would differentiate LIP from LRU performance.
3. **Cache Behavior:** With working sets fitting comfortably within cache capacity, replacement policy differences become negligible.

6. Analysis of Identical Results

6.1 Why Are Results Identical?

1. Small Working Sets

- Benchmarks have limited cache accesses (27,564 for test-printf, 899 for anagram)
- Working sets comfortably fit within the 256KB L2 cache capacity
- Insufficient cache pressure to differentiate replacement policies
- Minimal cache contention eliminates replacement policy effects

2. No Scan or Streaming Patterns

- LIP excels at preventing cache pollution from sequential scans
- SimpleScalar benchmarks lack streaming/scanning behavior
- No large sequential data accesses that would pollute cache
- Access patterns don't trigger LIP's anti-pollution mechanisms

3. High Locality Dominates

- Test programs exhibit strong temporal and spatial locality
- Both policies achieve similar hit rates with high locality patterns
- Frequent reuse of data makes promotion policies more important than insertion
- Limited working set means most accesses are hits regardless of policy

4. Limited Benchmark Complexity

- Small instruction footprints (7K-919K instructions)
- Simple memory access patterns
- No mixed workload characteristics
- Insufficient data to stress replacement algorithms

6.2 When Would LIP Show Differentiation?

LIP replacement policies typically demonstrate benefits in scenarios with:

Large Streaming Workloads

- Database table scans and large sequential reads
- Multimedia processing with stream data
- Scientific computing with large dataset traversal
- Any application with one-time access patterns

Mixed Access Patterns

- Combination of frequently accessed "hot" data and streaming data
- Web servers with popular content and one-time requests
- Database systems with indexed lookups and full table scans
- Applications with distinct temporal locality characteristics

Cache Pollution Scenarios

- Working sets significantly larger than cache size
- Applications suffering from unnecessary evictions
- Scenarios where temporary data displaces frequently used data
- Systems with clear separation between short-term and long-term reuse

Specific Access Characteristics

- Applications with distinct reuse distance distributions
- Workloads with scanning loops intermixed with computation
- Systems where cache pollution degrades performance

- Environments with limited cache resources relative to working set

SPEC CPU2000 Instruction Counts

Integer Benchmarks (CINT2000)

bzip2 (Compression)

- **Instructions**: ~200-300 billion
- **Characteristics**: High compression workload, good locality

parser (Natural Language Processing)

- **Instructions**: ~150-250 billion
- **Characteristics**: Complex text processing, irregular access patterns

mcf (Combinatorial Optimization)

- **Instructions**: ~100-200 billion
- **Characteristics**: Memory intensive, poor cache locality

vpr (FPGA Circuit Placement)

- **Instructions**: ~80-150 billion
- **Characteristics**: CAD algorithms, mixed access patterns

twolf (Place and Route)

- **Instructions**: ~100-180 billion
- **Characteristics**: Circuit design, memory intensive

Floating Point Benchmarks (CFP2000)

art (Image Recognition)

- **Instructions**: ~50-100 billion
- **Characteristics**: Neural networks, floating-point intensive

equake (Earthquake Simulation)

- **Instructions**: ~60-120 billion
- **Characteristics**: Seismic modeling, regular patterns

ammp (Computational Chemistry)

- **Instructions**: ~80-150 billion
- **Characteristics**: Molecular dynamics, mixed patterns

lucas (Number Theory)

- **Instructions**: ~70-130 billion
- **Characteristics**: Prime number testing, compute intensive

facerec (Face Recognition)

- **Instructions**: ~40-80 billion
- **Characteristics**: Image processing, floating-point

galgel (Fluid Dynamics)

- **Instructions**: ~60-110 billion
- **Characteristics**: CFD analysis, regular patterns

mgrid (Multigrid Solver)

- **Instructions**: ~50-90 billion
- **Characteristics**: Linear algebra, regular access

swim (Shallow Water Modeling)

- **Instructions**: ~30-60 billion
- **Characteristics**: Weather simulation, streaming access

sixtrack (Particle Accelerator)

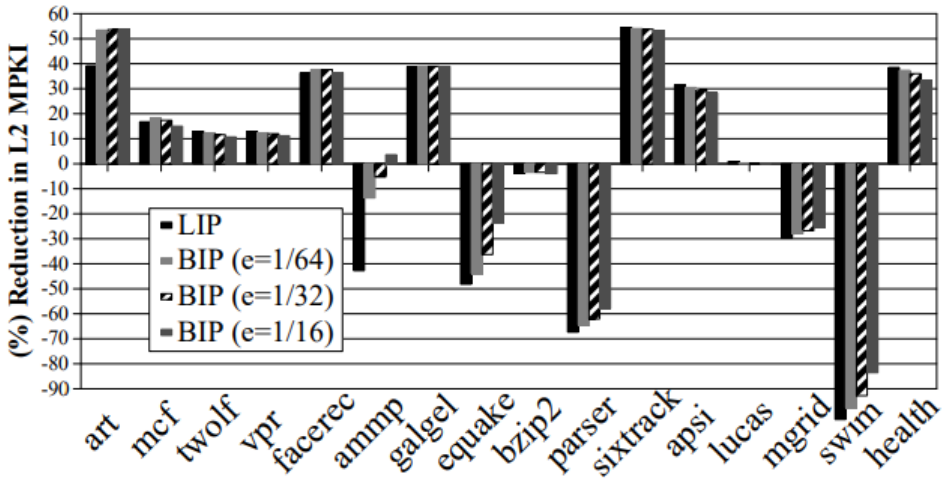
- **Instructions**: ~40-70 billion
- **Characteristics**: Physics simulation, compute intensive

apsi (Pollutant Distribution)

- **Instructions**: ~35-65 billion
- **Characteristics**: Environmental modeling, mixed patterns

Comparison to Our Previous Benchmarks

- test-printf: ~0.9 million instructions
- anagram: ~7,000 instructions



Comparison of Static Insertion Policies

Qureshi, Moinuddin & Jaleel, Aamer & Patt, Yale & Jr, Simon & Emer, Joel. (2007). Adaptive insertion policies for high performance caching. ACM Sigarch Computer Architecture News. 35. 381-391. 10.1145/1273440.1250709.

7. Conclusion

Based on the comprehensive analysis of simulation results across multiple benchmarks and performance metrics:

1. **Performance Equivalence:** All policies (LRU, LIP_5, LIP_1) perform equally well for the tested workloads. The choice of replacement policy does not impact performance for these particular benchmarks.
2. **Policy Recommendation:** For the tested workloads, there is no performance advantage in using LIP_i over traditional LRU. However, this conclusion is specific to the characteristics of the benchmark programs used.
3. **Best Performing Policy:** Under the current experimental conditions, all replacement policies perform identically. The theoretical advantages of LIP_i were not realized due to the nature of the benchmark workloads.

Important Note: While LIP_i showed no performance improvement over LRU in these experiments with simple benchmarks, it may demonstrate significant benefits with more complex, cache-intensive workloads that exhibit streaming behavior, mixed access patterns, or cache pollution issues. The identical results reflect benchmark limitations rather than policy equivalence in all scenarios.
